

**Question 1** (7 marks)

Defibrillators are used to apply an electric current to the heart. Defibrillators are made from two metal plates. During a charging process, one of the plates becomes positively charged and the other becomes negatively charged.

Question 1a (1 mark)

Select the particles that move to cause the charge on the defibrillator plates.

- Select
- Select
- Atoms
- Electrons
- Neutrons
- Protons

Question 1b (3 marks)

Question 1c (1 mark)

### Question 1b (3 marks)

A charged defibrillator with stored energy of 150 J applies a voltage of 300 V to an adult human. **Calculate** the current that would flow in 30 milliseconds.

**B** *I*  $\leftarrow$   $\rightarrow$      $\times_2$   $\times^2$   $\frac{1}{2}$   $\div$   $\Omega$   $\downarrow$

✓ Styles  $\downarrow$

### Question 1c (1 mark)

A gel is often applied between the plates and the patient's skin before using a defibrillator. **Suggest** why a gel is used.

**B** *I*  $\leftarrow$   $\rightarrow$      $\times_2$   $\times^2$   $\frac{1}{2}$   $\div$   $\Omega$   $\downarrow$

✓ Styles  $\downarrow$

**Question 1d** (2 marks)

One type of defibrillator uses charged plates which are stuck to the body of the patient with adhesive pads. Another type has plates that can be placed against the body of the patient by a doctor, who holds onto the plates using insulating grip handles. **Suggest** an advantage of each type of defibrillator.

Adhesive pads

Question 4 (10 marks)

An MYP student decides to investigate the motion of a simple model car made from a cotton reel. The image shows details of how the model was made.

After building the model car, the student turns the elastic band to wind it up and releases it. The model car travels along a horizontal tabletop.

As the model car is set in motion, video analysis software is used to track its movement frame by frame by placing dots on the screen at the end of the pencil. The software places one dot every 0.10 s.

Question 4a (2 marks)

**Calculate** the frequency with which the dots are placed.

**B** *I* ↵ ⇨    ×<sub>2</sub> ×<sup>2</sup>  $\frac{1}{2}$  = √ ∴ Ω √ ✓ Styles ∨

**Question 4c** (3 marks)

The student processed their data to calculate the velocity of the model car and drew a velocity-time graph, as shown below.

Question 5 (17 marks)

Question 5a (16 marks)

After completing the first experiment investigating the motion of a model car, a student wants to extend their investigation by measuring a different dependent variable.

**Design** a method to investigate the effect of changing the number of turns of the elastic band on the time taken for a model car to travel a fixed distance. In your plan, you must include:

- the independent variable, dependent variable, and one control variable
- a hypothesis
- details of any additional measuring equipment you will need to perform the experiment
- a detailed method for how you will collect the data
- details of how you will collect sufficient data.

**B** *I* ↵ ⇨    ×<sub>2</sub> ×<sup>2</sup> ∫ ∂ ∇ ∘ √ Styles ▾

**Question 5b** (1 mark)

The research question of the student in part (a) was:

How does the number of turns of the elastic band affect the time taken for a model car to travel a fixed distance?

Another student wants to carry out a different investigation using a similar model car.

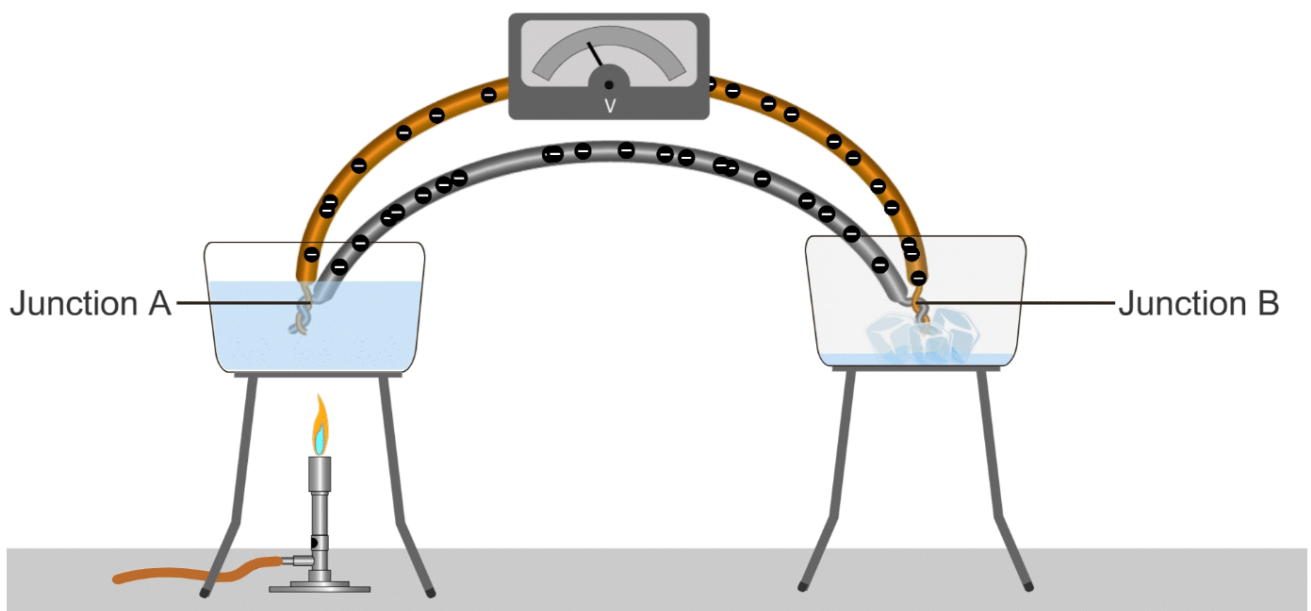

**Suggest** an alternative research question.

**Question 6** (23 marks)

The Seebeck effect is a phenomenon that happens when we connect two different metals to each other to form two junctions. When these metals are at different temperatures, a voltage is produced which causes an electric current to flow.

A student has a kit that uses the Seebeck effect to function. The kit contains a thermoelectric generator (TEG) which comprises two wires made of different metals. There are also two water tanks for hot and cold water.

The student wants to investigate the relationship between the voltage ( $V$ ) produced by the Seebeck effect and the temperature difference ( $\Delta T$ ).

**Question 6c** (1 mark)

The following data was collected from the experiment. **Calculate** the missing temperature difference and add your value to the table.

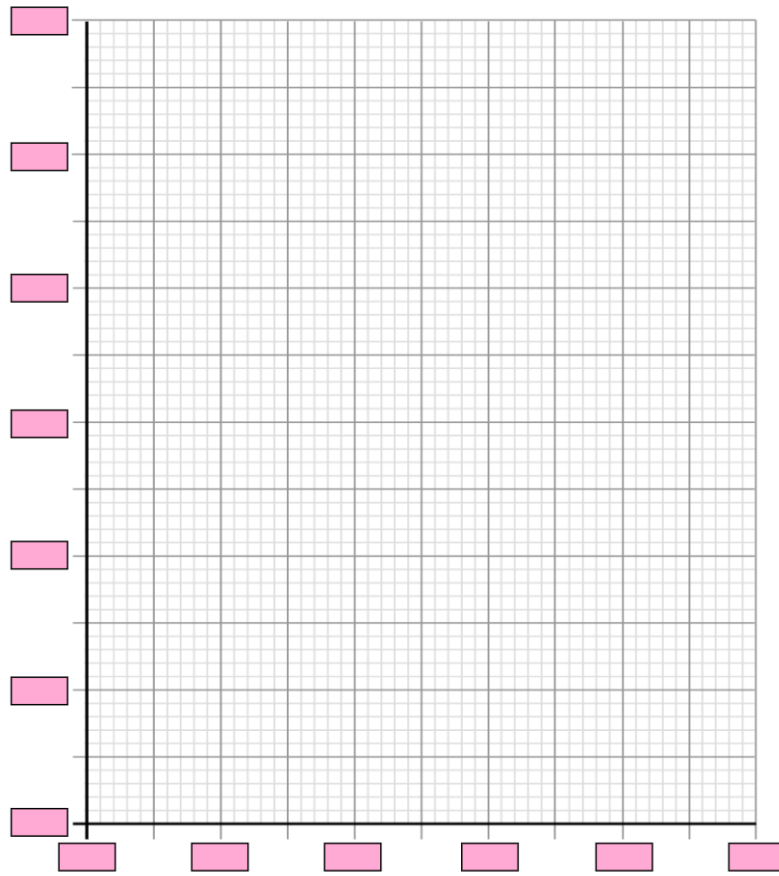

Temperature 1 / °C	Temperature 2 / °C	Temperature difference / °C	Voltage / V
52.6	7.6	45.0	0.298
47.0	7.0	40.0	0.251
43.4	7.8	35.6	0.206
36.9	8.1	28.8	0.131
32.1	12.1		0.054

**Question 6d** (4 marks)

**Present** the voltage versus temperature difference data in part (c) in a graph and add a line of best fit.

**Question 7c** (14 marks)

Newton's thought experiment enabled scientists to understand how artificial satellites could be placed in orbit. In 1945, science-fiction writer Arthur C Clarke suggested that artificial satellites orbiting the Earth could be used for a global communication system.

---

Geostationary satellites orbit the Earth once every 24 hours and permanently appear in the same location above the Earth's equator.

These satellites have to be placed at a specific distance from the Earth at an altitude of around 36 000 km, a region of space which is known as the 'Clarke Belt' after Arthur C Clarke.

Reaching this location is challenging and, due to the increase in global demand for satellite communication, this region is becoming increasingly crowded.

To work correctly, satellites must maintain a safe distance from each other. Spaces for new satellites are assigned by the International Telecommunication Union, an agency of the United Nations. This agency helps to settle disputes between countries or companies if satellites start to interfere with each other, which happens when they get too close together.

In 2022, there were estimated to be 539 satellites in this increasingly crowded area.

Most satellites in space are owned and operated by one company, SpaceX. In 2021, the company set a new record by launching 143 satellites into orbit on one rocket.

The prospect of one company having so much control over worldwide communication has raised concerns.

Satellites have wide-ranging applications in the modern world, such as wildfire control, espionage, wildlife tracking, surveillance and other civil or military applications.

---

**Question 8** (8 marks)

Satellites are put into orbit using rockets. However, space elevators have been proposed as an alternative method of putting objects into space.

---

If a cable was dropped from a large satellite in a geostationary orbit, it could be secured at one end to the Earth at the equator. The other end of the cable, out in space, could then be secured to a weight. If successful, the cable would stay straight due to the spinning motion of the Earth.

This cable could be used as part of a lifting device for a space elevator. A space elevator is one way that scientists believe objects could be lifted into space using electricity.

One of the main reasons why a space elevator has not been developed yet is that no material has been made that can withstand the extreme forces and environmental conditions involved.

In 2005, NASA launched a competition with a \$2 million dollar prize to see if anyone could develop a material strong enough to withstand the extreme forces, but none succeeded.

Continuing research by countries including China, Russia, the United States and Japan has seen progress.

A super-strong material made from carbon nanotubes could make the space elevator a reality.

Japan has tested moving a robotic device between two satellites linked together with a cable, modelling the movement of a future space elevator.

China is believed to have done similar experiments, although the results have not been shared.
